X Urea as a Partial Replacement of
Protein in Diet for Milk Goats XIvan L. Lindahl, Biochemist
Sheep, Goat and Fiber Section

Due to the action of the microorganisms in the rumen of sheep, cattle and goats, the nutritive requirements of these animals differ considerably from the non-ruminants or simple stomach animals. In addition to the action of the microorganisms in the digestion of fibrous feedstuffs, they can also synthesize certain vitamins, alter natural feedstuff proteins and synthesize proteins from non-protein nitrogen compounds.

For a number of years experiments have shown that urea and other non-protein nitrogen containing compounds can be used to replace a portion of the protein in diets for ruminants, with varying degrees of success. From the practical feeding angle these experimental observations can result in considerable profit to the livestock producer.

The supply of conventional protein concentrates has often been inadequate in recent years and high in cost and with the increasing livestock production combined with better feeding practices by the farmer, this situation would appear to become worse rather than improve in the future. Even during times of adequate protein supply these concentrates must, in general, be purchased by the livestock producer and protein is usually the most expensive single ingredient in the diet. Theoretically, urea can be produced in unlimited quantities and at a cost well below that for the same protein equivalent from conventional protein feedstuffs.

A large amount of experimental work has been done in studying the use of urea in diets for sheep and cattle, however, little work has been conducted with milk goats. Dr. J. T. Reid (J. Dairy Sci., Sept. 1953, Vol. 36, No. 9, pp. 955-996) has recently reviewed the extensive literature and has drawn the following conclusions:

(1) From the data considered as a whole (lambs and young cattle) urea is somewhat inferior to conventional protein supplements as a source of nitrogen for growth.

(2) Urea has not been a consistently effective substitute for protein in the diets of fattening lambs. Some data indicate that up to 25% of the diets containing 12% protein equivalent may be satisfactorily supplied by urea, but the feeding of urea at levels providing more than 25% of the nitrogen or when used in diets containing more than 12% protein equivalent has resulted in rather poor utilization of the urea.

(3) There is some evidence that a level of 1% urea in concentrate diets for fattening calves may be sufficiently unpalatable to reduce feed intake.

(4) Urea has been found to be a satisfactory substitute for about one-third of the nitrogen in diets for pregnant and lactating ewes.

(5) The results of a large number of long-time experiments with an appreciable number of dairy cattle have indicated that urea is a satisfactory replacement for conventional protein (fed at levels up to 2% of the required nitrogen) from the standpoint of milk yield and the maintenance of body weight. When used at levels up to 27% of the required nitrogen, no abnormal effects have been found in reproductive behavior, composition of the milk or general health. From a practical standpoint urea may safely compose up to 3% of the concentrate portion of the diet or up to 1% of the total diet for lactating dairy cattle.

Theoretically, urea should produce similar results when used in diets for milk goats, however, practical feeding tests were necessary to determine the value of urea as a partial protein replacement in diets for growth, gestation and lactation of milk goats. As palatability has been a problem at times when using urea diets for the feeding of calves, it was thought that this might be an acute problem with goats due to the fact that they are generally quite choosy in their eating habits. On the other hand, it was possible that urea might prove more useful for the growth of kids than for lambs because of the slower growth rate of kids and the much lower protein requirement for hair growth over that for wool production. To answer some of the questions regarding the usefulness of urea in the feeding of milk goats the following experiments were set up at the Agricultural Research Center, Beltsville, Maryland.

Growth Experiment

On November 5, 1953, 24 head of growing Toggenburg doe kids were divided into two lots. The division being made on the basis of weight, previous gain and genetic background. During the course of the experiment the two lots were handled in an identical manner except that one group received a concentrate mixture containing urea while the other group received a concentrate mixture containing linseed oil meal. The composition of the two concentrate diets is given as follows:

Control Diet - 16% Protein

| | |
|---------------------|------------|
| Ground yellow corn | 20 percent |
| Ground barley | 30 " |
| Wheat bran | 19 " |
| Blackstrap molasses | 10 " |
| Linseed oil meal | 20 " |
| Iodized salt | 0.75 " |
| Bonemeal | 0.25 " |

Experimental Diet - 16% Protein Equivalent

| | |
|----------------------|--------------|
| Ground yellow corn | 37.8 percent |
| Ground barley | 30.0 " |
| Wheat bran | 19.0 " |
| Blackstrap molasses | 10.0 " |
| Urea (feeding grade) | 2.2 " |
| Iodized salt | 0.75 " |
| Bonemeal | 0.25 " |

As urea contains no energy, the corn was increased to offset the loss of energy supplied by the linseed oil meal in the control diet. Both of the mixtures were pelleted using a 3/16 inch die.

On November 5 all animals received 1/2 pound of concentrate, 1 pound of alfalfa hay, and 2 pounds of orchard grass hay per day. The alfalfa hay contained 15.05% crude protein and the grass hay 6.69%. On November 9 the concentrate was increased to 3/4 pound per day, and on November 16, 1/2 pound of corn silage was added to the daily diet. The concentrate was increased to 1 pound per day on December 1 but was cut back to 3/4 pound on February 6. All animals had access to pasture from April 15 on. No other change was made in the diets until June 1 when the feeding of hay and silage was discontinued and the only roughage available being pasture. The weight record of the growing kids from November 5, 1953 to July 29, 1954, when the experiment was discontinued is given below:

Weight Record of Growing Doe Kids (pounds) Control Group (Linseed Oil Meal)

Gestation and Lactation Experiment

On November 18, 1953, 30 head of mature and yearling Toggenburg does were divided into 2 groups on the basis of former milk production, or milk production of their dams, age and length of gestation period. The data used for the division of the animals is given as follows:

Group 1 - Does

| Number | Age | Previous Milk Production | Production in Days | Length of Gestation Period |
|--------|----------------------|--------------------------|---------------------|----------------------------|
| 5D | 5 yrs. | 802.8 | 189.0 | 49 days |
| 36D | 5 yrs. | 857.0 | 150.0 | 48 " |
| 50D | 5 yrs. | 979.3 | 188.5 | 53 " |
| 48F | 3 yrs. | 465.5 | 161.0 | 48 " |
| 46F | 3 yrs. | 816.4 | 179.0 | 53 " |
| 25F | 3 yrs. | 870.6 | 201.0 | Not bred |
| 269 | 3 yrs. | 660.3 | 201.5 | 49 days |
| 39A | 8 yrs. <u>4.4</u> | <u>1289.5</u> 843 | <u>205.5</u> 184 | <u>15 "</u> 45 |

Yearling Does

| Number | Age | Dam | Dam's Production | Length of Gestation Period |
|--------|--------|-----|---------------------|----------------------------|
| 39G | 2 yrs. | 18E | 656.6 | 31 days |
| 12G | 2 yrs. | 35D | 909.7 | 56 " |
| 43G | 2 yrs. | 32C | 171.2 | 35 " |
| 24G | 2 yrs. | 27B | 746.6 | 34 " |
| 19G | 2 yrs. | 43D | 612.7 | 31 " |
| 28G | 2 yrs. | 23D | 907.8 | Not bred |
| 31G | 2 yrs. | 50D | <u>979.3</u> 712 | <u>Not bred</u> 37 |

The composite for milk production of the mature does and of the dams of the yearling does was 782 pounds. The composite for gestation time was 42 days and 3 animals not bred.

Group 2 - Does

| Number | Age | Previous Milk Production | Production in Days | Length of Gestation Period |
|--------|---------------|--------------------------|--------------------|----------------------------|
| 25D | 5 yrs. | 1317.3 | 188.5 | 18 |
| 43D | 5 yrs. | 612.7 | 183.5 | 52 |
| 35D | 5 yrs. | 909.7 | 187.5 | 55 |
| 8F | 3 yrs. | 426.5 | 181.0 | 56 |
| 37F | 3 yrs. | 818.4 | 198.0 | 56 |
| 36F | 3 yrs. | 608.8 | 195.5 | Not bred |
| 33E | 4 yrs. | 1216.0 | 187.5 | 53 |
| 78 | <u>5 yrs.</u> | <u>1080.1</u> | <u>144.5</u> | <u>11</u> |
| | 4.1 | 874 | 183 | 43 |

Yearling Does

| Number | Age | Dam | Dam's Production | Length of Gestation Period |
|--------|--------|-----|------------------|----------------------------|
| 11G | 2 yrs. | 35D | 909.7 | 53 |
| 38G | 2 yrs. | 18E | 656.6 | 56 |
| 6G | 2 yrs. | 22D | 599.6 | 53 |
| 10G | 2 yrs. | 34D | 451.2 | 52 |
| 9G | 2 yrs. | 54D | 813.3 | 15 |
| 29G | 2 yrs. | 5D | 802.8 | Not bred |
| 20G | 2 yrs. | 43D | <u>612.7</u> | <u>Not bred</u> |
| | | | 692 | 46 |

The composite for milk production of the mature does and of the dams of the yearling does was 789 pounds. The composite for gestation time was 44 days with 3 animals not bred.

Group 1 received the control diet or concentrate containing linseed oil meal while group 2 received the diet containing urea. The concentrate mixtures were the same as described under the growth experiment. The basic diet per doe was 1 pound of concentrate, $1\frac{1}{2}$ pounds alfalfa hay, 2 pounds of orchard grass hay, and 1 pound of corn silage per day, until February 14, 1954, when the concentrate was increased to $1\frac{1}{2}$ pounds per day. Further increases in the feeding of the concentrate in allowance for milk production was made on the following basis; 0.25 pounds of additional concentrate was allowed each doe for every pound of milk produced in excess of 4 pounds per day. All animals had access to pasture from April 15 on. The only other change in the feeding schedule was made on June 1, 1954, when the feeding of silage was discontinued. At kidding time the kids were removed from the does and each doe milked for a period of 120 days.

The weight record of the does from November 20, 1953 until June 4, 1954 is given as follows:

Control Diet (Linseed Oil Meal). Weight in pounds

| Doe | 11-20-53 | 12-18-53 | 1-15-54 | 2-12-54 | 3-12-54 | 4-9-54 | 5-7-54 | 6-4-54 |

| 78 | 4-5 | 3 | B=8.0, B=7.1 and D=6.5 | 21.6 |
| 25D | 4-18 | <u>1</u> | B=9.7 | <u>9.7</u> |
| | Total | 21 live kids | | 145.0 pounds |
| | | | Average weight of kids | 6.9 pounds |

Each doe with the exception of 10G from the experimental group, which failed to come into milk production, was milked for a total of 120 days. At the end of 120 days milking was discontinued and the doe removed from the experiment. Each doe was milked twice daily and a record of the milk yield in pounds was obtained. A milk sample was taken for fat analysis at the end of the first five days of production and samples were regularly taken from that time on at the middle of each production month.

The milk and butterfat production record for the two groups of does is given as follows:

Control Group (Linseed Oil Meal)

| Doe | Kidding date | Total Milk Production (lbs.) | Av. Daily Milk Production (lbs.) | Total Fat Production (lbs.) | 4% F.C.M. ^{1/} Production (lbs.) |
|-----|--------------|------------------------------|----------------------------------|-----------------------------|---|
| 12G | 2-18 | 329.3 | 2.74 | 8.60 | 260.7 |
| 269 | 2-19 | 689.9 | 5.75 | 25.87 | 664.0 |
| 50D | 2-20 | 920.5 | 7.67 | 27.70 | 783.8 |

Total milk production = 5,827.8 pounds
 Average milk production/doe = 529.8 pounds
 Total fat production = 185.22 pounds
 Average fat production/doe = 16.84 pounds
 Total 4% F.C.M. production = 5,109.5 pounds
 Average 4% F.C.M. production/doe = 464.5 pounds

^{1/} 4% fat corrected milk according to the Gaines-Davidson formula
 (FCM = $0.4M + 15F$, where M = weight of milk and F the weight of fat).

Experimental Group (Urea)

| Doe | Kidding date | Total Milk Production (lbs.) | Av. Daily Milk Production (lbs.) | Total Fat Production (lbs.) | 4% F. C. M. Production (lbs.) |

Total milk production = 7,457.8 pounds

Average milk production/doe = 678.0 pounds

Total fat production = 210.97 pounds

Average fat production/doe = 19.18 pounds

Total 4% F. C. M. production = 6,147.8 pounds

Average 4% F. C. M. production/doe = 558.9 pounds

Summary

Urea has been used to supply 36 percent of the protein equivalent in the concentrate diet for growth, gestation and lactation of milk goats with comparable results to that obtained with the use of linseed oil meal to supply the same protein equivalent. In none of the tests did the urea containing diet prove inferior to the diet containing linseed oil meal. Palatability was not a problem in any of the tests, i.e., in all cases the animals consumed the urea containing concentrate as readily as they did the concentrate containing linseed oil meal. Although every attempt was made to equalize the does selected for the lactation test, the factors affecting milk production in addition to nutrition are so complex that the increased milk production of the group receiving the urea diet should not be interpreted that urea is superior to linseed oil meal for milk production, however, the results of this test do indicate that urea can be used in diets for lactating does with very satisfactory results.

In the feeding trials described 2.2 pounds of urea plus 17.8 pounds of yellow corn replaced 20 pounds of linseed oil meal in the concentrate mixture. The economy of feeding urea would depend on the relative costs of the three ingredients. Using the price figures of feed delivered at the Agricultural Research Center, the urea plus corn for each ton of concentrate, cost \$17.80 as compared to \$18.20 for the linseed oil meal.

In practical feeding work the following facts should be taken into consideration before one attempts to feed urea:

- (1) Urea is toxic to animals in large quantities. It should not comprise more than 1 percent of the total diet or more than 3 percent of the concentrate mixture. Urea must be well mixed with the other constituents of the diet to prevent the animals from consuming excessive amounts.

- (2) Urea contains no energy while conventional protein supplements are good sources of energy. This fact needs to be taken into consideration when balancing diets.

- (3) Urea should only be considered as a replacement for expensive protein supplements and its use should result in reducing feed costs.
